

Project Sketch Idea 1

Reddit Video Game Analysis for Secondary Analysis

- Primary User: User Research Team
- Secondary Stakeholder/Users: Player insights and Marketing
- The Task: Scrub data from Reddit threads related to a particular video game or video game genre as a form of secondary analysis to examine a large scale of data regarding:
 - Sentiment
 - Usability issues
 - Game reception
 - New Mechanic reception
 - Competitive analysis with video games in the same genre
- Primary Interaction:
 - Would need to create a search function that pulls from specific Reddit boards related to video games or video game genres
 - Most likely would be a loop to create themes related to be sorted into categories for searches
- Data Input: Pulled from Reddit boards from specific video games and related video game genre boards
 - Can select a date range for when a post was made
 -
- Interface:
 - Website app on pythonanywhere.com since I am most familiar with Python.
 - Have a dashboard with a search bar
 - Instructions for how to search
- Results:
 - Would be a series of categories with themes that emerge underneath each category, and quotes or posts pulled from Reddit demonstrating the issue or positive feedback
 - Results would appear below the search bar and search instructions, organized into columns of categories, themes, and Reddit posts, with examples.
- Biggest Problem:
 - I plan to use this for Call of Duty so this could be a lot of data
 - Might need to narrow this down
 - I am still new to coding could be too much to do before my surgery
- What can I do on my own?
 - I know how to create a way to search the internet and pull search results
- Will I need help?
 - I might need help with taking it to the next step to pull out individual comments for examples of them
- Vignette:
 - A User Research team member logs into a PythonAnywhere web app and enters a video game title or genre into the search bar. They select relevant Reddit communities and apply a date range filter to focus on recent discussions.
 - After submitting the query, the system scrapes posts and comments from the selected Reddit threads. It then processes the data through a classification loop

that identifies patterns and organizes them into key categories, including sentiment, usability issues, game reception, new mechanic feedback, and competitive comparisons. These findings are then compared with the internal playtest to triangulate findings. It helps understand if this behavior or sentiment exists in a vacuum or is a larger-scale problem.

- The dashboard updates with results displayed beneath the search area in a structured layout. Each category contains emerging themes, supported by real Reddit quotes that illustrate player feedback.
- The researcher reviews the insights to quickly understand player sentiment and key issues, then shares findings with Player Insights and Marketing teams to inform product decisions, messaging, and competitive positioning.

Project Sketch Idea 2

Video game progression issue tracker

- Primary User: User Research Team
- Secondary Stakeholder/Users: Player insights
- The Task: upload reports from previous or current video games to track ongoing issues players have reported that have affected their:
 - Sentiment
 - Usability issues
 - Game reception
 - New Mechanic reception
 - Competitive analysis with video games in the same genre
- Primary Interaction:
 - Create a loop to search through reports for ongoing themes
 - Can be positive or negative themes
- Data Input:
 - Research Reports
 - Xcel documents
- Interface:
 - Website app on pythonanywhere.com since I am most familiar with Python.
 - Have an app you click on that takes you to the webpage
 - A button that allows you to search for a file path or drag and drop the file
 - You can select or drag and drop many files
 - Put in a “select date range” option for reports or Excel documents
- Results:
 - Would be a series of categories with themes that emerge underneath each category, and quotes or posts pulled from Reddit demonstrating the issue or positive feedback
- Biggest Problem:
 - A lot of this content is protected under NDA, so we need to make sure it is super secure
 - Probably need to have dummy data to create this with you
- What can I do on my own?
 - I think I can set up the loops and basic structure
- Will I need help?
 - I might need help with the date range function

- Creating the interface since I've never done that before
- How do I make it super secure?
- Vignette:
 - A User Research team member opens a PythonAnywhere web app and uploads multiple research reports and Excel files using a drag-and-drop interface or file selector. They apply a date range filter to focus on relevant time periods across studies.
 - Once the files are submitted, the system processes the documents through a classification loop that scans for recurring patterns and clusters them into themes. These themes are grouped into key categories such as sentiment, usability issues, game reception, new mechanic feedback, and competitive analysis.
 - The dashboard then populates with structured results, displaying categories alongside emerging themes and supporting excerpts from the uploaded reports. Positive and negative trends are surfaced, allowing the researcher to quickly identify persistent issues or improvements over time.
 - The researcher reviews the synthesized insights to track how player feedback has evolved across titles and shares key findings with Player Insights to inform future design and research priorities.

Project Sketch Idea 3

Quantitative analysis with a t-test over time of various video game player profiles.

- Primary User: User Research Team
- Secondary Stakeholder/Users: Player insights
- The Task: upload raw data to examine if there is a significant difference in sentiment over time or across reports of various video game player profiles regarding:
 - Sentiment
 - Usability issues
 - Game reception
 - New Mechanic reception
 - Competitive analysis with video games in the same genre
- Primary Interaction:
 - Create a loop to examine quantitative data of specific data
 - Run a statistical test: t-test to see if there is a statistical significance between the data of current or previous studies of player profiles
- Data Input:
 - Xcel documents of raw data
- Interface:
 - Website app on pythonanywhere.com since I am most familiar with Python.
 - Have an app you click on that takes you to the webpage
 - A button that allows you to search for a file path or drag and drop the file
 - You can select or drag and drop many files
 - Put in a "select date range" option for reports or Excel documents
- Results:
 - Would be a t-test showing if something is significantly significant of a video game mechanic or sentiment over time
 - See if there is statistical significance between independent groups to help determine if results occurred due to chance or reflect population differences between player profiles

- Biggest Problem:
 - A lot of this content is protected under NDA, so we need to make sure it is super secure
 - Probably need to have dummy data to create this with you
- What can I do on my own?
 - I think I can set up the loops and basic structure
- Will I need help?
 - I might need help with the date range function
 - Creating the interface since I've never done that before
 - How do I make it super secure?
 - Pull data from a document instead of the internet.
- Vignette:
 - A User Research team member opens a PythonAnywhere web app and uploads raw data files (Excel) containing player research across multiple studies. Using a drag-and-drop interface, they add several datasets and apply a date range filter to compare results over time or between player profiles.
 - After submitting the data, the system processes the datasets through a quantitative analysis pipeline. It organizes relevant variables (e.g., sentiment scores, usability ratings, or feature feedback) and runs t-tests to compare differences between groups over time.
 - The dashboard updates with clear statistical outputs, showing whether differences in sentiment, usability issues, game reception, or new mechanic feedback are statistically significant. Results include test statistics, significance levels, and indicators of whether observed differences are likely due to chance or reflect meaningful differences between player profiles.
 - The researcher uses these insights to validate trends seen in qualitative research and shares findings with developers to support data-driven decisions about game design and player segmentation.
